SUBSTITUTE BRIEF ON APPEAL

U.S. Patent and Trademark Office
Customer Service Window, Mail Stop Appeal Brief - Patents
Randolph Building
401 Dulany Street
Alexandria, VA 22314

Sir:

Appellants submit an original and two copies of this substitute Brief on Appeal. Appellants filed the original Brief on Appeal on March 11, 2005. A Notification of Non-Compliance with 37 C.F.R. § 41.37 was mailed November 30, 2005. We believe no fee is due. If this is incorrect, please charge our Deposit Account No. 19-0733.

I. REAL PARTY IN INTEREST

The real party in interest in U.S. Application No. 09/891,138 is Amgen, Inc.

II. RELATED APPEALS AND INTERFERENCES

There are no related appeals, interferences, or judicial proceedings.

III. STATUS OF THE CLAIMS

Claims 1-3 and 8-31 are canceled.

Claims 6 and 7 are rejected. This rejection is appealed.

IV. STATUS OF AMENDMENTS

Appellant filed an Amendment on August 11, 2004 with an accompanying Declaration under 37 C.F.R. § 1.132 by Daniel Lin, Ph.D. that was subsequent to a final rejection. The Advisory Action mailed September 7, 2004 states that the Response and Amendment filed August 11, 2004 was entered in full. The Advisory Action also states that the Declaration was received and taken into consideration.

Appellant filed an Amendment under 37 C.F.R. § 41.33(b)(1) on August 4, 2005 canceling claims 3, 13, 30, and 31. Appellant has not received an indication of the status of this amendment. This substitute Brief presumes entry of the amendment.

V. SUMMARY OF CLAIMED SUBJECT MATTER

The subject matter recited in claim 6 relates to isolated nucleic acids encoding a polypeptide comprising an amino acid sequence of SEQ ID NO:2. Pages 58 and 59; page 2, lines 1-2; page 3, lines 28-30.

The subject matter recited in dependent claim 7 relates to isolated nucleic acids which comprise the nucleotide sequence of SEQ ID NO:1. Page 3, lines 11-13.

VI. GROUNDS OF REJECTION TO BE REVIEWED ON APPEAL

Claims 6 and 7 stand rejected under 35 U.S.C. § 101 as allegedly lacking utility.

Claims 6 and 7 stand rejected under 35 U.S.C. § 112, first paragraph, as allegedly lacking enablement in view of the alleged lack of utility.

Claims 6 and 7 are rejected under 35 U.S.C. § 112, first paragraph, as allegedly lacking adequate written descriptive support.

VII. ARGUMENT

A. Rejection under 35 U.S.C. § 101 utility

1. Standards to Assess Utility

To satisfy the requirements of 35 U.S.C. § 101, an applicant must claim an invention that is "useful." The claimed invention satisfies the requirements for utility.

According to M.P.E.P. §2107, the Examiner must review the claims and the supporting written description to determine whether the utility requirement under 35 U.S.C. §101 is met. No rejection based on lack of utility should be made if an invention has a well-established utility, *i.e.*, a utility that will be immediately appreciated by one of ordinary skill in the art based on the characteristics of the invention, regardless of whether any such utility has been asserted. Neither should any rejection be made for lack of utility if an applicant has asserted a specific and substantial utility that would be considered credible by one of ordinary skill in the art.

In most cases, an applicant's assertion of utility creates a presumption of utility that will be sufficient to satisfy the utility requirement of 35 U.S.C. §101. M.P.E.P. §2107.02 III A.

The Court of Customs and Patent Appeals stated in *In re Langer*:

As a matter of Patent Office practice, a specification which contains a disclosure of utility which corresponds in scope to the subject matter sought to be patented must be taken as sufficient to satisfy the utility requirement of §101 for the entire claimed subject matter unless there is a reason for one skilled in the art to question the objective truth of the statement of utility or its scope.

In re Langer, 503 F.2d 1380, 1391, 183 U.S.P.Q. 288, 297 (C.C.P.A., 1974, emphasis in original). To overcome the presumption of sufficient utility as asserted by an applicant, the Examiner must carry the initial burden to make a *prima facie* showing of lack of utility and provide a sufficient evidentiary basis for the conclusion. In other words, the Examiner "must do more than merely question operability--[he] must set forth factual reasons which would lead one skilled in the art to question objective truth of the statement of operability." *In re Gaubert*, 524 F.2d 1222, 1224, 187 U.S.P.Q. 664, 666 (CCPA 1975).

As M.P.E.P. §2107.02 IV further states, a detailed explanation should be given for a utility rejection as to why the claimed invention has no specific and substantial asserted utility. Documentary evidence should be provided when possible. Otherwise the Examiner should specifically explain the scientific basis for his factual conclusions.

2. Rejection of claims 6 and 7

Claims 6 and 7 were rejected under 35 U.S.C. § 101 as allegedly lacking utility. Appellant respectfully traverses this rejection and argues that the rejection is improper. The present invention resides, in part, in the identification of TGR18 nucleic acids. The invention satisfies utility under 35 U.S.C. § 101 because the identification of TGR18 nucleic acids permits one of skill in the art to analyze modulators of TGR18. Such modulators can be used, *e.g.*, for altering TGR18 function in the kidney and for the treatment of kidney-related conditions such as hypertension.

In the Final Office Action mailed February 20, 2004 the Examiner concedes that the invention has a credible utility (section 12, page 14) but alleges that Appellant has not provided sufficient evidence of a specific and substantial utility. The Examiner argues that Appellant has not established anything specific about the receptor such as its tissue of origin or "the properties of the claimed GPCR" (section 10, page 3 of the Final Office Action). Furthermore, he contends that the Declaration under 37 C.F.R. § 1.132 by Daniel Lin filed October 15, 2003 ("Lin Declaration I"; Exhibit 1 of the Evidence Appendix) to provide additional evidence of the utility of the claimed invention merely shows that a polypeptide having a sequence of SEQ ID NO:2, which is encoded by SEQ ID NO:1, can increase intracellular calcium. The Examiner concludes that this showing

does not establish a specific utility because many GPCRs modulate changes in intracellular calcium when generally stimulated (section 10, page 3 of the Final Office Action). The Examiner also argues that the asserted utility is not substantial, as further research is required to determine how to use the claimed receptor.

The rejection for lack of utility was maintained in the Advisory Action mailed September 7, 2004. The Examiner alleged that a second Declaration under 37 C.F.R. § 1.132 by Daniel Lin filed August 11, 2004 ("Lin Declaration II", Exhibit 2 of the Evidence Appendix) was considered, but again failed to provide sufficient evidence of specific and substantial utility.

3. The asserted utility is specific, substantial, and credible

As described in the present application, the present inventors cloned, for the first time, the mouse polynucleotide sequence encoding a GPCR referred to in the specification as "TGR18." The inventors also identified the amino acid sequence of mouse TGR18 and determined the tissue-specific expression pattern of TGR18 mRNA (*e.g.*, pages 55, 58 and 59).

The specification further teaches that mouse TGR18 is a GPCR (*see, e.g.*, page 10, lines 11-19); that mouse TGR18 is abundantly expressed in the kidney (*see, e.g.*, page 7, lines 7-9); and that TGR18 can participate in the modulation of cellular function in cells, for example kidney cells, in which it is expressed (*see, e.g.*, page 51, lines 31-34). The specification also discloses that a GPCR that is predominantly expressed in the kidney can play a role in renal disease, *e.g.*, hypertension (*see, e.g.*, page 52, lines 2-6) and in modulating kidney cell function (*see, e.g.*, page 7, lines 7-8 and 12-14). The specification also teaches that TGR18 can be used to identify modulators of GPCR activity and that GPCR activity can be assessed using a variety of assays to determine functional effects (*see, e.g.*, the section beginning on page 29). These include changes in calcium ion levels (*see, e.g.*, page 11, lines 8-10 and page 39, lines 27-30).

As further evidence that TGR18 has GPCR activity, Appellant provided Lin Declaration I. The Declaration presents data demonstrating that murine TGR18, which is encoded by SEQ ID NO:1, has a known G-protein coupled receptor activity, *i.e.*, it transduces an increase in intracellular calcium. As Dr. Lin explains, GPCR activity can be assessed using a variety of

common assays. One such assay is an Aequorin assay, which is widely used in the art to measure GPCR-mediated increases in intracellular calcium. The data provided in the Lin Declaration I establish that mouse (encoded by the coding region of SEQ ID NO:1), human, and rat TGR18 GPCR all transduce an increase in intracellular calcium.

As explained in the section summarizing the rejections, the Examiner argued that Lin Declaration I was insufficient to establish a specific utility because many GPCRs can transduce an increase in cellular calcium, and there was no evidence that succinic acid was biologically significant in the kidney and did not serve merely as a general stimulator of GPCR activity.¹ Although Appellant believes that the Lin Declaration I, which provided data showing that mouse TGR18 is a functional GPCR, is more than sufficient to support the asserted utilities, further evidence, *i.e.*, a post-filing publication, that TGR18 has biological activity in kidney function was provided in Appellant's response mailed on August 11, 2004.

The publication (He *et al.*, *Nature*, 429:188-193, 2004; Exhibit 3 of the Evidence Appendix of this brief) describes that mouse GPR91 has GPCR activity. Mouse GPR91 corresponds to TGR18. See Lin Declaration II, which accompanied the August 11, 2004 response (Exhibit 2 of the Evidence Appendix of this brief). He *et al.* also teach that the role of succinate as a ligand for a GPCR was an unexpected finding (*see, e.g.*, the Abstract, page 188, column 1). Accordingly, succinate is not regarded by those in the art as a general stimulator of GPCR activity. Thus, the Examiner's speculations that succinate may be a general stimulator of GPCR activity, which were presented in response to Lin Declaration I, are unfounded. TGR18 is, in fact, specifically activated and therefore has a specific function.

He *et al.* also describe earlier work in the field that provides a biologically relevant context for succinate and consequently, TGR18, in the kidney. For example, succinate was known to increase the re-absorption of phosphate and glucose into the proximal tubule (*see*, page 192, the first full paragraph of column 1). Further, succinate-treated kidney culture *ex vivo* release renin

¹ Succinic acid was the ligand in the experiments summarized in the Lin Declaration I; the ligand was not disclosed in the specification.

(page 191, first column, last paragraph). These effects were known prior to the filing date of the application, as evidenced by the publication dates of the references cited at the indicated passages.

Moreover, He *et al.* provide data showing that succinate induces hypertension in normal mice. In GPR91-deficient animals (*i.e.*, TGR18-deficient animals), however, succinate did not induce hypertension (*see, e.g.*, page 191, second column, last paragraph). Thus, He *et al.* provide additional data demonstrating the biological relevance of TGR18 in the kidney, as taught in the instant application. In view of the biological role of TGR18 and its demonstrated GPCR function, TGR18 nucleic acid and polypeptides sequences have credible, substantial, and specific uses.

Specific utility

Specific utility is defined by the M.P.E.P. as a utility that is specific to the subject matter claimed. The M.P.E.P. explains that applications show sufficient specific utility when applicants disclose a “specific biological activity” and reasonably correlate that activity to a “disease condition.” M.P.E.P. §§2107.01 and 2107.02. In the present application, Appellant identifies the nucleic acid and amino acid sequences of mouse TGR18, demonstrates the expression pattern of TGR18, and discloses that TGR18 plays a role a “disease condition” (*e.g.*, hypertension, page 52, lines 2-6) that correlates with a “biological activity” (*i.e.*, GPCR activity). The application provides methods for identifying compounds capable of modulating TGR18 activity and therefore for modulating TGR18 in a biological context *in vivo*, *e.g.*, in the kidney. Appellant thus submits that the present invention has a utility that is specific for the claimed TGR18 GPCRs.

Substantial utility

The Examiner's position that the asserted utility is not substantial because more research is required to determine how to use the claimed (section 10, page 3 and bridging to page 4 of the Final Office Action) is also unfounded.

A substantial utility defines a real world use (M.P.E.P. §2107.01.I). This invention provides TGR18 polynucleotide and polypeptide sequences. As explained above, the application teaches that TGR18 is expressed in the kidney and that kidney-specific GPCRs can function in diseases such as hypertension. The application further teaches how to identify agonists and

antagonists of TGR18. Appellant has provided additional evidence as to the biological significance of TGR18 *in vivo*. The present invention therefore has a real-world use in modulating the physiology of tissues, *e.g.*, kidney, in which TGR18 is expressed. Accordingly, the utilities satisfy the "substantial" criterion for utility.

4. Finding Sufficient Utility in the Present Application is Consistent with the Policy of Encouraging Early Disclosure

Our patent law places much emphasis on encouraging early disclosure of inventions. This is a particularly relevant policy consideration in case law involving the utility standard under 35 U.S.C. §101. In *Nelson v. Bowler*, 626 F.2d 853, 206 U.S.P.Q. 881 (C.C.P.A. 1980), the C.C.P.A. was confronted with a situation where the claimed compound, 16-phenoxy-substituted prostaglandin (PG), was shown to have some pharmacological activity, *i.e.*, causing changes in blood pressure in the rat blood pressure (BP) test and stimulation of smooth muscles in the gerbil colon smooth muscle stimulation (GC-SMS) test, yet no specific therapeutic use for the compound was established. In deciding the question of utility, the C.C.P.A. stated:

Knowledge of the pharmacological activity of any compound is obviously beneficial to the public. It is inherently faster and easier to combat illness and alleviate symptoms when the medical profession is armed with an arsenal of chemicals having known pharmacological activities. Since it is crucial to provide researchers with an incentive to disclose pharmacological activities in as many as compounds as possible, we conclude that adequate proof of any such activity constitute a showing of practical utility.

Nelson, 626 F.2d at 856, 206 U.S.P.Q. at 883. The present case is analogous to *Nelson*. TGR18 has a physiological functions in the kidney, and compounds capable of modulating TGR18 are useful as agents for regulating its function. Assays for screening for GPCR modulators and evaluating their function, including in model systems such as mouse model systems, are thus beneficial to the public and the disclosure of how to perform these assays should be encouraged. The present application provides just this kind of disclosure. A holding that the present invention lacks sufficient utility under 35 U.S.C. §101 to warrant patent protection would be inconsistent with the underlying policy

discussed in the case law and would create a strong disincentive for researchers to disclose their inventions of this type.

5. Summary

TGR18 nucleic acid and polypeptide sequences have credible, specific, and substantial utility. The utility rejection under 35 U.S.C. §101 is therefore improper and should be reversed.

B. Rejection Under 35 U.S.C. § 112--enablement

Claims 6 and 7 were rejected as not being enabled, on the ground that the claimed invention is not supported by a specific and substantial asserted utility or a well-established utility. As discussed above, the claimed invention has a credible, specific and substantial utility under the examination guideline set forth in the M.P.E.P. The utility-based enablement rejection under 35 U.S.C. §112, first paragraph, is therefore improper and should be withdrawn.²

C. Rejection under 35 U.S.C. § 112, written description

1. Standards for written description

The first paragraph of 35 U.S.C. § 112 requires that the specification provide a written description of the claimed invention:

[t]he specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same, and shall set forth the best mode contemplated by the inventor of carrying out his invention.

The purpose of the written description requirement is to ensure that the specification conveys to those skilled in the art that the applicants possessed the claimed subject matter as of the filing date

² The remainder of the enablement rejection is moot in view of the cancellation of claims 3, 13, 30, and 31.

sought. *Vas-Cath Inc. v. Mahurkar*, 935 F.2d 1555, 1563-64, 19 U.S.P.Q.2d 1111, 1117 (Fed. Cir. 1991).

The Federal Circuit has expressly considered the application of the written description requirement to inventions in the field of biotechnology. See, *University of California v. Eli Lilly & Co.*, 119 F.3d 1559, 43 U.S.P.Q.2d 1398 (Fed. Cir. 1997). The Court held that the written description requirement can be fulfilled in any number of ways, so long as the specification describes the invention in sufficient detail that one skilled in the art can clearly conclude that the inventor invented the claimed invention. For a chemical invention, an adequate description "requires a precise definition, such as by structure, formula, chemical name, or physical properties...." (119 F.3d at 1568, 43 U.S.P.Q.2d at 1406.) The Court also addressed the manner by which a genus of cDNAs might be described, when it stated:

A description of a genus of cDNAs may be achieved by means of a recitation of a representative number of cDNAs, defined by nucleotide sequence, falling within the scope of the genus or of a recitation of structural features common to the members of the genus, which features constitute a substantial portion of the genus.

Id., 43 U.S.P.Q.2d at 1406.

Written description requirement in the context of DNA-related inventions has been further discussed by the Federal Circuit in *Enzo Biochem. Inc. v. Gen-Probe Inc.*, 296 F.3d 1316, 63 U.S.P.Q.2d 1609 (Fed. Cir. 2002). In *Enzo*, the Court defined a standard where "the written description requirement can be met by 'showing that an invention is complete by disclosure of sufficiently detailed, relevant identifying characteristics . . . i.e., complete or partial structure, other physical and/or chemical properties, functional characteristics when coupled with a known or disclosed correlation between function and structure, or some combination of such characteristics.'" F.3d 1316 at 1324, 63 U.S.P.Q.2d at 1613.

2. Claims 6 and 7 are adequately described

In the present case, the claims are drawn to isolated TGR18 nucleic acids that encode a polypeptide that has a G protein coupled receptor activity. Structural features are set forth in the

claims, *i.e.*, reference nucleic acid or amino acid sequences. Thus, the claim language defines physical and structural properties of the invention, as explicitly required by the Court in *University of California v. Eli Lilly & Co.* Furthermore, the polypeptides have a function, *e.g.*, the ability to transduce an increase in intracellular calcium. Contrary to the Examiner's assertion that Appellant has not described a useful invention, the claimed invention does, in fact, meet the requirement for utility, as demonstrated above. The Examiner's argument that the facts here are different from the *University of California v. Eli Lilly & Co.* and that no useful or enabled TGR18 nucleic acids are described is therefore totally unfounded.

Claim 6 recites an isolated nucleic acid encoding a polypeptide comprising an amino acid sequence of SEQ ID NO:2. It has been established by the courts that, because the genetic code is widely known, a disclosure of an amino acid sequence provides sufficient information such that one would accept that an applicant was in possession of the full genus of nucleic acids encoding a give amino acid sequence (*see, e.g., In re Bell*, 991 F.2d 781, 26 U.S.P.Q.2d 1529 (Fed. Cir. 1993)).

Claim 7 recites an isolated nucleic acid that comprises SEQ ID NO:1. SEQ ID NO:1 clearly provides a precise structural feature of the claimed nucleic acids.

3. Summary

Claims 6 and 7 meet the written description requirement. The rejection of these claims under 35 U.S.C. § 112 ¶ 1 for lack of written description is therefore improper and should be reversed.

D. Conclusion

For the reasons given above, the rejections of claims 6 and 7 should be reversed.

Respectfully submitted,

Lisa M. Hemmendinger
Reg. No. 42,653

Customer No. 22907
December 29, 2005

VIII. CLAIMS APPENDIX

Claims involved in the appeal:

6. An isolated nucleic acid encoding a polypeptide comprising an amino acid sequence of SEQ ID NO:2.

7. The isolated nucleic acid of claim 6, wherein the nucleic acid comprises the nucleotide sequence of SEQ ID NO:1.

IX. EVIDENCE APPENDIX

1. Declaration Under 37 C.F.R. 1.132 by Daniel Lin, Ph.D. (Lin Declaration I)
 - a) filed with Appellant's amendment dated October 15, 2003
 - b) entry of the amendment was acknowledged in the Office Action dated February 20, 2004
2. Declaration Under 37 C.F.R. § 1.132 by Daniel Lin, Ph.D. (Lin Declaration II)
 - a) filed on August 11, 2004 with Appellant's amendment after final rejection
 - b) The Advisory Action mailed September 7, 2004 stated that the amendment and response filed August 11, 2004 was entered in full and the Declaration was taken into consideration.
3. Weihal He et al., "Citric acid cycle intermediates as ligands for orphan G-protein-coupled receptors," Nature (13 May 2004) 429: 188-193
 - a) submitted on August 11, 2004 with Appellant's amendment after final rejection
 - b) The Advisory Action mailed September 7, 2004 stated that the amendment and response filed August 11, 2004 was entered in full and the Declaration was taken into consideration.
4. U.S. Patent No. 5,871,963
 - a) submitted in Appellant's IDS dated October 9, 2001
 - b) initialed by Examiner April 8, 2003
 - c) cited in Appellant's amendment filed August 11, 2004 after final rejection
 - d) The Advisory Action mailed September 7, 2004 stated that the amendment and response filed August 11, 2004 was entered in full and the Declaration was taken into consideration.

X. RELATED PROCEEDINGS APPENDIX

There are no related proceedings.

DECLARATION UNDER 37 C.F.R. /1.132
BY DANIEL LIN, PH.D.

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Sir:

1. I, Daniel Lin, Ph.D., am a scientist at Tularik Inc., a biopharmaceutical company headquartered in South San Francisco, CA and the assignee of the above-referenced patent application. I am the inventor of the subject matter disclosed and claimed in the above-referenced patent application.
2. I hold a Ph.D. from the Massachusetts Institute of Technology (1999). I have worked in the field of G protein-coupled receptors for about four years.
3. It is my understanding that the claims currently under examination, which relate to, *inter alia*, murine TGR18 nucleic acid sequences, were rejected as allegedly lacking utility. This

Application Serial No. 09/891,138
Page 2

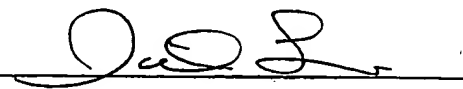

Declaration presents exemplary data showing that TGR18 functions as a GPCR. The experiments were performed by myself or under my supervision.

4. GPCR activity can be assessed using a variety of common assays. One such assay is an Aequorin assay. Aequorin assays are widely used in the art to measure GPCR-mediated increases in intracellular calcium. The assay involves the use of the Ca^{2+} -sensitive photoprotein aequorin. The aequorin complex contains the apo-aequorin protein, molecular oxygen, and the luminophore coelenterazine. The binding of calcium ions disrupts the complex, leading to the emission of blue light, which provides a means of determining increases in intracellular calcium.

5. Mouse, human, and rat TGR18 GPCR activities were tested in an Aequorin assay. Briefly, CHO cells were transiently co-transfected with 10 μg of an Aequorin reporter gene and 10 μg of a cDNA encoding human TGR18, mouse TGR18, rat TGR18, or a vector control. The mouse TGR18 expression vector comprises the coding region of the cDNA sequence presented in SEQ ID NO:1, which encodes the protein of SEQ ID NO:2. Following transfection, the cells were harvested and re-suspended in buffer containing coelenterazine f. Aequorin luminescence was determined following incubation of the harvested cells with ligand. The results, shown in Figure 1, demonstrate that mouse, human, and rat TGR18 all have GPCR activity: they each transduce an increase in intracellular calcium.

6. I further declare that all statements made herein of my knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements are made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment or both (18 U.S.C./1001), and may jeopardize the validity of the patent application or any patent issuing thereon.

The citric acid cycle is central to the regulation of energy homeostasis and cell metabolism¹. Mutations in enzymes that catalyse steps in the citric acid cycle result in human diseases with various clinical presentations². The intermediates of the citric acid cycle are present at micromolar concentration in blood and are regulated by respiration, metabolism and renal reabsorption/extrusion. Here we show that GPR91 (ref. 3), a previously orphan G-protein-coupled receptor (GPCR), functions as a receptor for the citric acid cycle intermediate succinate. We also report that GPR99 (ref. 4), a close relative of GPR91, responds to α -ketoglutarate, another intermediate in the citric acid cycle. Thus by acting as ligands for GPCRs, succinate and α -ketoglutarate are found to have unexpected signalling functions beyond their traditional roles. Furthermore, we show that succinate increases blood pressure in animals. The succinate-induced hypertensive effect involves the renin-angiotensin system and is abolished in GPR91-deficient mice. Our results indicate a possible role for GPR91 in renovascular hypertension, a disease closely linked to atherosclerosis, diabetes and renal failure^{5,6}.

In a search for natural ligands for orphan GPCRs, we tested extracts from various animal tissues for their ability to evoke an increase in intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) using the aequorin assay⁷. We found that fractions from pig kidney extracts specifically activated cells expressing GPR91 (Fig. 1a). GPR91 is an orphan GPCR highly expressed in the kidney and shares 33% amino acid identity with GPR99/GPR80 (refs 4, 8). On the basis of their homology with the purinergic receptor P2Y1, nucleotide ligands were predicted for GPR91 and GPR99 (ref. 4). However, the GPR91 ligand activity in pig kidney extracts was resistant to various stringent treatments including alkaline phosphatase, peptidase, and hydrolysis in 6 M HCl at 100 °C. Accordingly, the supposition that GPR91 might be activated by a nucleotide or peptide ligand was unlikely. We purified the natural ligand for GPR91 by ion-exchange, size-exclusion and reversed-phase fast performance liquid chromatography/high-performance liquid chromatography (Fig. 1a).

A major molecular ion $[M + H]^+$ at m/z 119.2 was observed by mass spectrometry (Fig. 1b). ¹H NMR analysis revealed a single type of proton in the highly purified GPR91 ligand (Fig. 1c). ¹³C NMR analysis further suggested the presence of $-CH_2-$ (methylene) and $=C=O$ (carbonyl) groups (Fig. 1d). Combined with mass spectrometry results and the biochemical properties of the ligand, the purified GPR91 ligand was predicted and confirmed to be succinic acid (Fig. 1c, d).

Commercially obtained succinate (the physiological form of succinic acid) increased $[Ca^{2+}]_i$ dose-dependently in the aequorin assay (Fig. 2a). Succinate also activated mouse and rat orthologues of GPR91 (Fig. 2a). The succinate-induced increase in $[Ca^{2+}]_i$ was further confirmed with a fluorimetric imaging plate reader (FLIPR) system in the 293-hGPR91 cell line (293 cells stably expressing human GPR91) (Fig. 2b). The concentration giving half-maximal response (EC_{50}) for succinate-induced activation of human GPR91 was $56 \pm 8 \mu M$ in the aequorin assay and $28 \pm 5 \mu M$ in the FLIPR assay. GPR91 was selectively activated by succinate but not by other citric acid cycle intermediates (Supplementary Information) or any of a collection of 800 pharmacologically active compounds and known GPCR ligands tested (data not shown). Furthermore, of 200

carboxylic acids and structurally related analogues, succinate was found to be the most potent in increasing $[Ca^{2+}]_i$ (a representative subset is summarized in Supplementary Information).

Because GPR99 is the closest homologue of GPR91, we proposed that other citric acid cycle intermediates and carboxylic acids might activate GPR99. We identified α -ketoglutarate as a ligand for human GPR99, with an EC_{50} of $69 \pm 11 \mu M$ in the aequorin assay (Fig. 2c) and $32 \pm 4 \mu M$ in the FLIPR assay (Fig. 2d). α -Ketoglutarate also activated mouse GPR99 (Fig. 2c). Neither succinate nor α -ketoglutarate activated calcium mobilization with about 30 GPCRs unrelated to GPR91 and GPR99 (data not shown).

To dissect the signalling pathways of GPR91 and GPR99, various biochemical assays were investigated. Succinate inhibited forskolin-stimulated cAMP production in 293-hGPR91 cells, an effect abolished by preincubation with pertussis toxin (PTX) (Fig. 2e). In addition, succinate induced the accumulation of inositol phosphate in 293-hGPR91 cells (Fig. 2f). The succinate-induced accumulation of inositol phosphate and an increase in $[Ca^{2+}]_i$ were each partly inhibited by pertussis toxin (Fig. 2f and Supplementary Information). Moreover, succinate activated extracellular signal-regulated kinase (Erk) in 293-hGPR91 cells (Supplementary Information). Taken together, these results suggest that GPR91 activation by succinate couples to at least two signalling pathways, a pertussis-toxin-sensitive G_i/G_o pathway and a pertussis-toxin-insensitive G_q pathway. Similarly, α -ketoglutarate stimulated inositol phosphate formation in a GPR99-dependent manner (Fig. 2g).

Because GPR99 activation did not affect cAMP levels (data not shown), and both inositol phosphate formation (Fig. 2g) and $[Ca^{2+}]_i$ flux (Supplementary Information) were found to be insensitive to pertussis toxin, GPR99 seems to act exclusively through a G_q -mediated pathway.

Ligand-induced receptor internalization is often characteristic of GPCR activation and signal attenuation⁹. Immunofluorescent staining of cells expressing Flag-tagged GPR91 or GPR99 revealed that both GPR91 and GPR99 were localized to the plasma membrane (Fig. 2h). Ligand stimulation induced the internalization of both receptors (Fig. 2h).

Because the dicarboxylate groups of succinate and α -ketoglutarate are required for the activation of GPR91 and GPR99, we speculated that basic residues of GPR91 and GPR99 might be important in binding dicarboxylate ligands. A partial three-dimensional model of GPR91 was generated. Mutation of Arg 99, His 103, Arg 252 or Arg 281 (Supplementary Information) abolished GPR91 activation by succinate, whereas mutation of His 249, Arg 255 or Tyr 107 had no effect on receptor function (Fig. 3a). Various GPR91 mutants were expressed at similar levels (Fig. 3b) and localized at the plasma membrane (data not shown). All four residues required for GPR91 activation by succinate (Arg 99, His 103, Arg 252 and Arg 281) are directed into the central cavity where *cis*-retinal binds in the rhodopsin structure (Fig. 3c, d). These four positively charged residues cluster together, Arg 99 and His 103 of helix III on one side and Arg 252 of helix VI and Arg 281 of helix VII on the other side,

and may provide a unique electrostatic complementary binding environment for succinate (Fig. 3d). A comparison of about 300 family A GPCRs revealed that GPR91 and GPR99 uniquely contain all four basic residues, suggesting that GPR91 and GPR99 are specialized receptors for dicarboxylate ligands.

Expression analysis by quantitative reverse-transcriptase-mediated polymerase chain reaction (Q-RT-PCR) revealed that the GPR91 and GPR99 messenger RNAs were each predominantly expressed in the kidney, with limited expression in other tissues (GPR91 in the liver and the spleen, and GPR99 in the testis and the smooth muscle; Fig. 4a, b and refs 3, 4). *In situ* hybridization experiments indicated specific GPR91 and GPR99 expression in the cortical region of the mouse kidney (Fig. 4c). GPR91 was detected mainly in the proximal tubules, as demonstrated by the presence of a prominent brush border projecting into the lumen on periodic acid–Schiff-stained adjacent sections (Fig. 4d). GPR91 was also found, to a smaller extent, in the distal tubules (revealed by staining with antibodies against the distal-tubule marker calbindin¹⁰; Fig. 4d) and the juxtaglomerular apparatus (Supplementary Information). In contrast, GPR99 was found predominantly in the distal tubules (Fig. 4e, f).

Intravenous injection of succinate into Sprague–Dawley rats increased plasma renin activity (Fig. 5a), which is consistent with a previous report that succinate-treated kidney cultures *ex vivo* released renin¹¹. Renin is a key enzyme in the renin–angiotensin

system, which is essential in blood pressure regulation^{12,13}. Cumulative intravenous administration of succinate produced a dose-dependent increase in mean arterial pressure (MAP) (Fig. 5b). Bilateral nephrectomy completely abolished this effect (Fig. 5c), demonstrating the kidney as the primary site of action. To dissect the pharmacological mechanism for succinate-induced hypertension, the angiotensin-converting enzyme inhibitor captopril was used. Pretreatment with captopril significantly attenuated the hypertensive effect of succinate (Fig. 5d), indicating that the angiotensin-converting enzyme product(s) might mediate hypertension induced by succinate. In contrast, neither nephrectomy nor captopril treatment had any effect on angiotensin II-induced hypertension (Fig. 5c, d).

To further explain the mechanisms underlying succinate-induced hypertension, we generated GPR91-deficient mice by homologous recombination (Fig. 5e, f). Mice homozygous for the targeted allele of GPR91 are viable and have no discernable phenotype. The systolic blood pressures and heart rates were similar in unanaesthetized wild-type and GPR91-deficient mice (Fig. 5g; systolic blood pressures were 129.5 ± 1.5 mmHg for wild-type and 131.2 ± 2.4 mmHg for GPR91-deficient mice; heart rates were 613 ± 12.4 beats min^{-1} for wild-type and 606 ± 11.4 beats min^{-1} for GPR91-deficient mice). However, succinate could no longer induce hypertension in GPR91-deficient mice (Fig. 5h, i). In contrast, angiotensin II increased blood pressure similarly in wild-type and

GPR91-deficient mice (Fig. 5h, i), indicating that the hypertensive effect of succinate might be mediated by GPR91.

Succinate and α -ketoglutarate are normally present in mitochondria, but are found in circulation with mean plasma levels of about 5 μ M for succinate and about 25 μ M for α -ketoglutarate^{14–16}. Succinate is known to increase the reabsorption of phosphate and glucose into the proximal tubule¹⁷ and to stimulate gluconeogenesis¹⁸. Accumulation of extracellular succinate is observed in physiological and/or pathophysiological states linked to the deterioration of blood supply, such as ischaemia^{19,20}. It is known that the renovascular hypertension is often associated with restricted blood supply to the kidney owing to the obstruction of renal arteries in diseases such as atherosclerosis⁵. It is possible that the accumulation of succinate in ischaemic conditions might contribute to stenosis-associated hypertension through the activation of GPR91. Although we have shown that the hypertensive effect of succinate is mediated by GPR91 through the activation of the renin–angiotensin system, the molecular mechanism of renin release by succinate is not clear. Because GPR91 is a G_q - and G_i -coupled receptor, it is unlikely that GPR91 functions directly on the juxtaglomerular cells to stimulate renin release, which is usually triggered by G_i activation²¹. It remains to be investigated whether sympathetic nerve activity, prostaglandins or nitric oxide²² might provide an indirect mechanism for succinate-induced renin release. The presence of GPR91 in the liver and the spleen might also have functions in mediating these effects.

Thus, we have identified succinate as the natural ligand for GPR91, and α -ketoglutarate as the ligand for the homologous receptor GPR99. We have shown that intermediates in the citric acid cycle function as signalling molecules, engendering renewed interest in a biochemical pathway discovered more than 60 years ago. We have provided evidence that the pro-hypertensive effect of succinate is mediated by GPR91 and involves the renin–angiotensin system. GPR91 activation by succinate might therefore provide a link between energy homeostasis/metabolic status and haemodynamic regulation. The finding that intermediates in the citric acid cycle are GPCR ligands should facilitate the understanding of molecular links of the citric acid cycle to metabolic diseases, such as hypertension, atherosclerosis and diabetes, and the design of novel drugs with GPR91 and GPR99 as molecular targets. □

Methods

Purification of GPR91 ligand

Pig kidneys (6 kg; Pel-Freez) were homogenized and extracted in ethanol/water/acetic acid (50/46/4, by vol.). The supernatant was freeze-dried, resuspended in 10 mM K_2HPO_4 , pH 8.0, applied to an XK50/20 Q Sepharose anion-exchange column (Amersham), and developed with a 0–0.25 M NaCl linear gradient. The active fractions were subjected to three more steps of purification: a Hilo 26/60 Superdex30 size-exclusion column (developed in Hank's buffered saline at pH 7.35); a Superdexpeptide HR10/30 size-exclusion column (developed in 0.1% trifluoroacetic acid/water); and a C_{18} 4.6 mm \times 250 mm reverse-phase column (developed in 0.1% trifluoroacetic acid/water). The active fractions from the final purification step were freeze-dried and dissolved in H_2O for NMR and mass spectrometry analysis.

NMR and mass spectrometry

The 1H and ^{13}C NMR spectra were recorded on a Bruker Avance DRX700 spectrometer (Bruker Analytik GmbH) at 700 and 176 MHz, respectively. The mass spectrum was obtained on an HP 1100MSD spectrometer (Agilent Technologies) with electrospray ionization in positive detection mode. A full-scan mass spectrum covering the m/z range 50–500 was acquired.

Cell culture and signalling assays

Chinese hamster ovary (CHO) cells were transiently transfected with 5 μ g GPCR and 5 μ g aequorin reporter gene⁷ in 100-mm dishes as described²³. Aequorin luminescence was recorded with a Microplate (Berthold). FLIPR assays were performed on FLIPR384 with a FLIPR calcium assay kit (Molecular Devices). Inositol phosphate formation was assayed as the incorporation of 3H -myo-inositol as described^{23,24}. Cells were stimulated with compounds in the presence of 10 mM LiCl for 40 min at 37 °C before the addition of 20 mM formic acid. cAMP assay was performed with the cAMP-Screen system (Applied Biosystems). Cells were stimulated for 20 min with 10 μ M forskolin before treatment with compounds for a further 20 min at 37 °C. Anti-phospho-Erk and anti-Erk monoclonal antibodies were obtained from New England Biolabs. Anti-Flag and anti-tubulin

antibodies were obtained from Sigma. Western blots were detected with the ECL Plus detection system (Amersham). For some studies, 100 ng ml⁻¹ pertussis toxin (Calbiochem) was incubated with cells for 16 h.

Immunofluorescence staining

Human embryonic kidney 293 cells transfected with Flag-tagged GPR91 or GPR99 were plated on poly-(D-lysine)-treated slides. Cell-surface staining and ligand-induced internalization was performed as described⁹. Internalization of GPR91 or GPR99 was induced for 10 min by succinate (200 μ M) or α -ketoglutarate (300 μ M) at 37 °C.

In situ hybridization, immunohistochemistry and expression analysis

These were performed as described^{10,25}. [³²P]UTP-labelled antisense or sense RNA probes for mouse GPR91, GPR99 or renin were hybridized to paraformaldehyde-fixed, paraffin-embedded mouse kidney sections. For periodic acid–Schiff and renin staining, adjacent mouse kidney sections were used. For co-localization with calbindin on the same tissue section, slides were incubated with anti-calbindin antibody (Sigma) and developed with Vectastain avidin–biotin–complex kit (Vector Lab) with 3,3'-diaminobenzidine as substrate before hybridization *in situ*. Sections were counterstained with haematoxylin or toluidine blue. Q-RT-PCR was performed on an ABI Prism 7700 sequence detector using Taqman Gold kit (Applied Biosystems). Ratios of GPR91 or GPR99 to glyceraldehyde-3-phosphate dehydrogenase mRNA were calculated. Primer and probe sequences for GPR91 and GPR99 are available from the authors on request.

Receptor model

The published bovine rhodopsin structure was used as a template for generating a partial GPR91 structure model²⁶. The GPR91 primary sequence was aligned to bovine rhodopsin (PDB code 1F88; Supplementary Information), and the three-dimensional homology model was generated with the Modeller program.

In vivo experiments

All experiments were performed under protocols approved by the Institutional Animal Care and Use Committee. Animals were housed in a temperature-controlled room under a 12 h light–dark cycle with water and standard rodent chow available *ad libitum*. Blood pressure was measured in unanaesthetized animals by the tail-cuff method or in pentobarbital-anesthetized animals by the intra-arterial method for those involving chemical administration^{27,28}. Male Sprague–Dawley rats (about 300 g; Harlan) or mice (about 30 g; Lexicon) were used. Systolic blood pressure was recorded in mice for 5 days; at least 20 measurements were made daily with a BP-2000 blood pressure analysis tail-cuff system (Visitech Systems). The mean systolic blood pressure and pulse rate were taken for each animal. Intra-arterial measurement of blood pressure was achieved with a polyethylene PE50 (for rats) or a stretched PE10 (for mice) catheter implanted into the carotid artery, with another implanted into the jugular vein before the experiments. The artery catheter was connected to a high-sensitivity isometric transducer (Harvard Apparatus) for continuous recording of blood pressure. MAP data were acquired by Ponemch Physiology Platform (Gould Instrument). The venous catheter was used for chemical administration. Bilateral nephrectomy was performed as described²⁹. Captopril (10 mg kg⁻¹) was given as a bolus injection 30 min before the administration of succinate. Plasma renin activity was determined by radioimmunoassay as the rate of angiotensin I generation (DiaSorin). GPR91-deficient mice were generated by homologous recombination in embryonic stem cells (Lexicon). Results are expressed as means \pm s.e.m. Statistical significance was evaluated by Student's *t*-test or two-way analysis of variance, followed by Dunnett's *post-hoc* test. Differences resulting in $P < 0.05$ were considered significant.

Aquaporin-0 membrane junctions reveal the structure of a closed water pore

The lens-specific water pore aquaporin-0 (AQP0) is the only aquaporin known to form membrane junctions *in vivo*¹. We show here that AQP0 from the lens core, containing some carboxy-terminally cleaved AQP0^{2,3}, forms double-layered crystals that recapitulate *in vivo* junctions. We present the structure of the AQP0 membrane junction as determined by electron crystallography. The junction is formed by three localized interactions

between AQP0 molecules in adjoining membranes, mainly mediated by proline residues conserved in AQP0s from different species but not present in most other aquaporins. Whereas all previously determined aquaporin structures show the pore in an open conformation^{4–9}, the water pore is closed in AQP0 junctions. The water pathway in AQP0 also contains an additional pore constriction, not seen in other known aquaporin structures^{4–9}, which may be responsible for pore gating.

AQP0 is a member of the aquaporin family, members of which form pores that are either highly selective for water (aquaporins) or also permeable to other small neutral solutes such as glycerol (aquaglyceroporins) (reviewed in ref. 10). To date, the atomic structures of three aquaporins have been determined (AQP1^{4–6}, GlpF^{7,8} and AQPZ⁹). Sequence alignment shows AQP0 to be closely related to the pure water channel AQP1 (43.6% identity, 62.6% similarity). The presence of His 172, a residue conserved only in aquaporins but substituted in aquaglyceroporins, also suggests that AQP0 forms a pure water pore. AQP0 water permeability at neutral pH is approximately 40 times lower than that of AQP1¹¹, but AQP0 water conductance doubles under mildly acidic conditions¹². In the case of aquaporins in plant roots, a pH-dependent closure of the water pores has been reported¹³. Thus, evidence suggests that certain aquaporin pores are gated.

AQP0 water pores are considered essential for the lens micro-circulation system, proposed to supply deeper-lying fibre cells with nutrients and to clear waste products^{14,15}. Unlike all other aquaporins, AQP0 is also present in membrane junctions. It is particularly enriched in the 11–13 nm thin junctions between lens fibre cells, that feature square AQP0 arrays¹. Atomic force microscopy analysis of *in vitro* reconstituted AQP0 two-dimensional crystals demonstrated these crystals to be double-layered¹⁶.

Using AQP0 from the core of sheep lenses, where some of the AQP0 is proteolytically cleaved near the C terminus at various sites in an age-dependent manner^{2,3}, we reproduced the double-layered two-dimensional crystals^{16,17}. When core AQP0 was reconstituted at a lipid-to-protein ratio of 0.25 (w/w), large membrane sheets formed (>6 μ m) that in some cases showed two parallel edges, revealing them to be double-layered (Fig. 1a). The crystals showing p422 symmetry had lattice constants of $a = b = 65.5$ Å and a thickness of 11 nm (Fig. 2a), the same dimensions as thin junctions in the lens¹. Double-layered AQP0 two-dimensional crystals are therefore likely to recapitulate thin lens fibre cell junctions.

Electron diffraction analysis of AQP0 crystals (tilted to an angle of up to 70°) produced strong diffraction spots to 3 Å resolution in all directions (Fig. 1b, c; the electron crystallographic data are summarized in Table 1). As the crystal structure of the homologous bovine AQP1 was available⁵, we determined the structure of the AQP0 membrane junction by molecular replacement, thus avoiding the cumbersome and time-consuming process of collecting high-resolution images of tilted specimens. Sequencing of cloned sheep AQP0 showed an identical amino acid sequence to bovine AQP0¹⁸, with the exception of three conservative (S20T, M90V and S240T) and one non-conservative substitutions (C14F).

Our model (Fig. 2a) shows unique features that enable AQP0 to form membrane junction interactions. These differ from those previously suggested based on atomic force microscopy data¹⁶. The extracellular surface of AQP0 is rather flat and the interactions are mediated by direct contacts of the corresponding loops in the opposing AQP0 molecules (Fig. 2a). Loop C, connecting α -helices three and four, is significantly shorter than in AQP1 and GlpF. The shortened loop C (also seen in AQP2, AQP5, AQP6 and AQP8) is crucial for the formation of the very tight AQP0 junction, as it allows three specific interactions to be formed that are mediated almost exclusively by proline residues.

The most striking interaction involves Pro 38, in extracellular loop A. The proline residues (Pro 38) from eight symmetry-related AQP0 molecules in the stacked tetramers come together to form a

Applicant hereby **appeals** to the Board of Patent Appeals and Interferences from the last decision of the examiner.

The fee for this Notice of Appeal is (37 CFR 1.17(b))

\$330.

☐ Applicant claims small entity status. See 37 CFR 1.27. Therefore, the fee shown above is reduced by half, and the resulting fee is:

\$.

☐ A check in the amount of the fee is enclosed.

☐ Payment by credit card. Form PTO-2038 is attached.

☐ The Director has already been authorized to charge fees in this application to a Deposit Account. I have enclosed a duplicate copy of this sheet.

☒ The Director is hereby authorized to charge any fees which may be required, or credit any overpayment to Deposit Account No. 20-1430 in accordance with the accompanying Fee Transmittal PTO/SB/17 submitted in duplicate.

☒ A petition for an extension of time under 37 CFR 1.136(a) (PTO/SB/22) is enclosed. Please deduct the fee in accordance with the accompanying Fee Transmittal PTO/SB/17 submitted in duplicate.

WARNING: Information on this form may become public. Credit card information should not be included on this form. Provide credit card information and authorization on PTO-2038.

I am the

☐ applicant/inventor.

☐ assignee of record of the entire interest.
See 37 CFR 3.71. Statement under 37 CFR 3.73(b) is enclosed.
(Form PTO/SB/96)

☒ attorney or agent of record.

Registration number 44,879

☐ attorney or agent acting under 37 CFR 1.34(a).

Registration number if acting under 37 CFR 1.34(a) _____
